Abstract

Real world decision making is like a puzzle having complex, uncertain and vague information and this fact portray the wide range applicability of grey system theory in decision making procedure as grey system theory deals with the systems having information with uncertainty. In order to extend the base-criterion method to uncertain conditions, grey information may be a better way to solve a lot of multi-criteria decision-making problems. In this paper, we proposed a novel approach ‘grey base-criterion method’ (GBCM) based on the linguistic variables extended to the grey information. Weights of criteria have been calculated using GBCM. Numerical examples are illustrated and then the results are compared by the grey best-worst method (GBWM). Results of comparison show the high reliability of GBCM method with less consistency ratio over GBWM. A real case study of the fastest growing OTT (Over the Top) platforms in India has been taken to bestow the robustness of the proposed method.

Keywords: Grey system theory, Grey-base-criterion method, Group multi-criteria decision making, Pairwise-comparison, Over the Top (OTT) platform.

1. Introduction

Multi-Criteria Decision Making (MCDM) has been developed as an important part of operational research. In decision-making, solver must choose best solution from the given set of good solutions (Korhonen, 1992). The MCDM methods can be categorized into two main parts: first, to allocate the weights to all the criteria under consideration; second, by ranking alternatives based on their performance. Over the periods, many MCDM methods has been developed by researchers and decision makers. Methods including ranking of alternatives are, TOPSIS (Technique for the Order Preference by Similarity to Ideal Solution) (Hwang and Youn, 1981), VIKOR
(Višekriterijumska Optimizacija i Kompromisno Resenje) (Opricović, 1998), SWARA (Step-wise Weighted Assessment Ratio Analysis) (Keršuliene et al., 2010), PROMETHEE (Preference Ranking Organization Method for Enrichment Evaluation) (Brans and De Smet, 2016) and ELECTRE (Elimination and Choice Expressing REality) (Kumar et al., 2017). Many MCDM methods involving allocation of weights to criteria are introduced as AHP (Analytic Hierarchy Process) (Satty, 1990), ANP (Analytic Network Process) (Saaty, 2004), BWM (Best Worst Method) (Rezaei, 2015), and BCM (Base-Criterion Method) (Haseli et al., 2020).

The BCM method was first introduced by Haseli et al. (2020), in which one criteria among different criteria selected as base criterion. Then the pairwise comparison between base-criterion and other criteria is done by using numerical scale from 1/9 to 9. Other pairwise comparison is done by using $a_{\text{Base},i} \times a_{i,j} = a_{\text{Base},j}$. Further a min-max model is obtained to calculate the weights of criteria. Main advantages of BCM are that it includes less pairwise comparison and low inconsistency ratio which gives better solution for any real-world problem. This method has been used in many real-world problems such as supplier selection (Ayough et al., 2023), and stock selection (Narang et al., 2021; Narang et al., 2022b).

It has been noticed that there is uncertainty and ambiguity in real-world decision-making problems. So, it will be a right step to extend MCDM methods into uncertainty or poor information. Grey System Theory was given by Julong (1989). A grey system is made of partial known information and partial unknown information. Known information lies under white number and unknown information lies under black number. In between black and white numbers there are grey numbers. So, the concept of grey number has been used for incomplete information system. This fact inspires to introduce the grey system theory in several MCDM methods for solving real-world problems (Datta et al., 2013; Kose et al., 2013; Bai and Sarkis, 2013; Kaviani et al., 2020). Fuzzy set theory (Zadeh, 1996) is also an approach to deal with uncertain and doubtful decision-making problems. Several tools have been proposed as interval-valued fuzzy set, type-2 fuzzy set, intuitionistic fuzzy set, linguistic fuzzy set and hesitant fuzzy set (Han and Trimi, 2018; Guo and Zhao, 2017; Mardani et al., 2015; Dožić et al., 2018; Narang et al., 2022a).

In the current study, the base-criterion method has been extended to grey information. The obtained results are compared with GBWM. The result calculated by GBCM is more reliable than the one calculated in GBWM (Mahmoudi et al., 2020). Computation with grey numbers is much easier than other uncertainty systems. After that the proposed approach has been employed to the OTT platforms to rank the alternatives. In the next section, the basic concepts of grey number system are discussed in detail.

2. Material and methods

2.1 Preliminaries

A number whose exact value is unknown but the range or interval in which it lies is known referred as grey number. A grey number can be expressed as $\otimes A = [\underline{a}, \overline{a}]$, $\underline{a} < \overline{a}$, where $\underline{a}$ is lower bound and $\overline{a}$ is upper bound of grey number $\otimes A$. Length of grey number can be calculated as $\overline{a} - \underline{a}$.

2.1.1 Properties

A grey number have neither lower bound nor upper bound is called a black number, i.e., $\otimes A = [-\infty, +\infty]$, here $\otimes A$ is a black number.

A grey number have same lower bound as well as upper bound is called a white number, i.e., $\otimes A = [\underline{a}, \overline{a}]$, and $\underline{a} = \overline{a}$.

Core or kernel of a grey number is:

$$\tilde{\otimes A} = \frac{1}{2}(\overline{a} + \underline{a})$$

If $\otimes A = [\underline{a}, \overline{a}]$ and $\otimes B = [\underline{b}, \overline{b}]$, the arithmetic operations on grey numbers are:
\begin{align*}
\otimes A + \otimes B &= [a + b, \tilde{a} + \tilde{b}], \\
\otimes A - \otimes B &= [a - \tilde{b}, \tilde{a} - \tilde{b}], \\
\otimes A \otimes B &= \left[\text{Min}\{ab, \tilde{a}\tilde{b}, \tilde{a}b, a\tilde{b}\}, \text{Max}\{ab, \tilde{a}\tilde{b}, \tilde{a}b, a\tilde{b}\}\right], \\
\otimes A^{-1} &= \left[\frac{1}{\tilde{a}}, \frac{1}{\tilde{a}}\right] \\
\text{The grey possibility degree } P(\otimes A \leq \otimes B) &= \frac{\text{Max}(0, L(\otimes A) + L(\otimes B) - \text{Max}(0, a+b))}{L(\otimes A) + L(\otimes B)}
\end{align*}

2.1.2 Grey linear programming

Grey linear programming is a mathematical model to get the best solution from the set of solutions. In real-world problems, the input data suffers from a certain degree of uncertainty or incompleteness. So, this problem may handle with grey number system. If a decision maker is taking grey numbers as input data in any linear model then this is an example of grey linear programming.

Dang and Forrest (2009) presented a positioned programming method for solving GLP model which covers all the uncertainties from the input which is grey number.

Positioned programming method for solving grey linear programming problem is:

\[ \text{Max} S = C(\otimes)X \]
\[ \text{s.t.} \]
\[ A(\otimes)X \leq b(\otimes), \]
\[ X \geq 0. \]

\[ C(\otimes) = [C_1(\otimes), C_2(\otimes), ..., C_n(\otimes)]^T, \]
\[ b(\otimes) = [b_1(\otimes), b_2(\otimes), ..., b_m(\otimes)]^T, \]
\[ A(\otimes) = \begin{bmatrix}
    a_{11}(\otimes) & a_{12}(\otimes) & \cdots & a_{1n}(\otimes) \\
    a_{21}(\otimes) & a_{22}(\otimes) & \cdots & a_{2n}(\otimes) \\
    \vdots & \vdots & \ddots & \vdots \\
    a_{m1}(\otimes) & a_{m2}(\otimes) & \cdots & a_{mn}(\otimes)
\end{bmatrix} \]

(1)

Where \(A(\otimes)\) is the grey consumption matrix, \(C(\otimes)\) is the grey price vector, \(b(\otimes)\) is the grey constraint vector, and \(X\) is the problem decision vector.

\[ c_j(\otimes) \in [c, \tilde{c}], \ c \geq 0, j = 1,2, ..., n \]
\[ b_i(\otimes) \in [b, \tilde{b}], b \geq 0, i = 1,2, ..., m. \]
\[ a_{ij}(\otimes) \in [a, \tilde{a}], a_{ij} \geq 0, i = 1,2, ..., m, j = 1,2, ..., n. \]

to solve the grey linear programming, whitenization of grey number is done.

**Definition 1.** White values of grey parameter can be determined as

\[ c_j'(\otimes) = \rho_jc + (1 - \rho_j)c; \ j = 1,2, ..., n, \]
\[ b_i'(\otimes) = \beta_i\tilde{b} + (1 - \beta_i)b; \ i = 1,2, ..., m, \]
\[ a_{ij}'(\otimes) = \delta_{ij}\tilde{a}_{ij} + (1 - \delta_{ij})a_{ij}; \ i = 1,2, ..., m; \ j = 1,2, ..., n. \]

where \(\delta_{ij}, \beta_j\), and \(\rho_j\) (\(i = 1, ..., m\) and \(j = 1, ..., n\)) lies in the closed interval [0,1].

Then,

\[ \text{Max} S = C'(\otimes)X \]
\[ \text{s.t.} \]
\[ A'(\otimes)X \leq b'(\otimes), X \geq 0. \] (2)

is called a positioned programming of grey linear programming where \(\delta_{ij}, \beta_j\), and \(\rho_j\) (\(i = 1,2, ..., m\) and \(j = 1,2, ..., n\)) are positioned coefficient of consumption vector, constraint vector for resource and off price vector, respectively.
**Definition 2.** When $\rho = \beta = 1, \delta = 0$ then programming model is called ideal model. For these values we get lowest values for the model.

**Definition 3.** When $\rho = \beta = 0, \delta = 1$ then programming model is called critic model. For these values we get highest values of the model.

### 2.2 Grey BCM method – The Proposed method

In this section all the steps of GBCM methods has been described in detail as follows:

- **Step 1.** Certify the criteria set for decision making. This step includes specification of desired criteria $(C_1, C_2, \ldots, C_n)$ for any real-world decision-making problem.
- **Step 2.** Certify the base criterion. In this step decision maker chooses one criteria from the set of criteria as a base-criterion.
- **Step 3.** Determine the pairwise comparison of base criterion with all other criteria. In this step relative importance of the base criterion over all the criteria’s is done by using grey linguistic terms in Table 1.

#### Table 1. Pairwise comparison using grey number

<table>
<thead>
<tr>
<th>Linguistic variable</th>
<th>Grey Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equally Important (EI)</td>
<td>[1,1]</td>
</tr>
<tr>
<td>Weakly Important (WI)</td>
<td>[2,3]</td>
</tr>
<tr>
<td>Fairly Important (FI)</td>
<td>[4,5]</td>
</tr>
<tr>
<td>Very Important (VI)</td>
<td>[6,7]</td>
</tr>
<tr>
<td>Absolutely Important (AI)</td>
<td>[8,9]</td>
</tr>
</tbody>
</table>

**Step 4.** Calculate the optimal weights of the criteria $(w_1, w_2, \ldots, w_n)$. The optimal weight for each $w_B/w_j$ will be equal to $a_{Bj}$ for all values of $j$. The problem can be expressed as follows:

$$
\begin{align*}
\text{Min} \ & \max \ |w_B - a_{Bj}| \\
\text{s.t.} \ & \sum_j w_j = 1 \\
& w_j \geq 0, \forall j
\end{align*}
$$

(3)

We can rewrite this equation as:

$$
\begin{align*}
\text{Min} \ & \xi \\
\text{s.t.} \ & |w_B - a_{Bj}| \leq \xi, \forall j \\
& \sum_j w_j = 1 \\
& w_j \geq 0, \forall j
\end{align*}
$$

(4)

To convert non-linear model into linear model McCormick method has been used for linearization. Following steps has been involved:

1. If $\phi_1 = x_1 x_2$ and $x_1 \in [x_1^L, x_1^U], x_2 \in [x_2^L, x_2^U]$ for converting non-linear model into linear, following assumption are considered.

   $$
   \phi_1 = w_j \xi, \quad w_j \in [0,1]
   $$

   Where, $\xi = CI \times CR$. The value of CR belongs to [0,1]. Inconsistency ratio should be less than equal to specified value $A$, so we can write,

   $$
   \xi = [0, CI \times A], \quad CI \geq 0, \quad 0 \leq A \leq 1.
   $$
Then adding the given constraints to our model, it is converted into linear model:
\[
\begin{align*}
\phi_1 &\geq x_1^l x_2 + x_2^l x_1 - x_1^u x_2^u, \\
\phi_1 &\geq x_1^u x_2 + x_2^u x_1 - x_1^l x_2^l, \\
\phi_1 &\leq x_1^l x_2 + x_2^u x_1 - x_1^u x_2^l, \\
\phi_1 &\leq x_1^u x_2 + x_2^l x_1 - x_1^l x_2^u.
\end{align*}
\]
and we get the final grey linear model as:
\[
\begin{align*}
\min & \xi \\
\text{s.t.} & \quad \bigotimes w_B - \bigotimes w_j \otimes a_{Bj} \leq \bigotimes \phi_1 \quad \forall \ j, \\
& - \bigotimes w_B + \bigotimes w_j \otimes a_{Bj} \leq \bigotimes \phi_1 \quad \forall \ j, \\
& \bigotimes \phi_1 \geq 0, \\
& \bigotimes \phi_1 \geq \bigotimes \xi + CI.A \otimes w_j - CI.A, \\
& \bigotimes \phi_1 \leq CI.A \otimes w_j, \\
& \bigotimes \phi_1 \leq \xi, \\
& w_j - w_j \geq \varepsilon, \forall \ j, \\
& \sum_j \bigotimes w_j = [0.8, 1.2], \\
& \bigotimes w_j \geq 0, \forall \ j, 0 \leq A \leq 1, CI \geq 0.
\end{align*}
\] (5)

To obtain the grey optimal weights, grey linear model can be solved by using positioned programming method.

Step 5. To aggregate the weight of each criteria we used grey geometric mean.
\[
\bigotimes w_j = \left( w_{1j}, w_{2j}, \ldots, w_{kj} \right)^i
\]
Step 6. Now the calculated weights are normalized by using following equation.
\[
\bigotimes w_j^* = \left( \frac{w_1}{\sum_{j=1}^{n} w_j + \sum_{j=1}^{n} w_2} \right)^i \left( \frac{w_2}{\sum_{j=1}^{n} w_j + \sum_{j=1}^{n} w_2} \right)
\] (6)
Step 7. To compare the grey weights grey possibility degree is used.
\[
GP_{ij} = \begin{bmatrix}
P(\bigotimes A \leq \bigotimes A) & P(\bigotimes B \leq \bigotimes A) & \cdots & P(\bigotimes N \leq \bigotimes A) \\
P(\bigotimes A \leq \bigotimes B) & P(\bigotimes B \leq \bigotimes B) & \cdots & P(\bigotimes N \leq \bigotimes A) \\
\vdots & \vdots & \ddots & \vdots \\
P(\bigotimes N \leq \bigotimes A) & P(\bigotimes B \leq \bigotimes A) & \cdots & P(\bigotimes N \leq \bigotimes N)
\end{bmatrix}
\] (7)
We can further write this matrix as:
\[
P_{ij} = \begin{bmatrix}
P_{AA} & P_{BA} & \cdots & P_{NA} \\
P_{AB} & P_{BB} & \cdots & P_{NB} \\
\vdots & \vdots & \ddots & \vdots \\
P_{AN} & P_{BN} & \cdots & P_{NN}
\end{bmatrix}
\] (8)
where, \( P_{ij} = \begin{cases} 
1 & \text{if } i \leq j \leq 0.5, \quad i, j = A, \ldots, N \\
0 & \text{if } i \leq j \leq 0.5, \quad i, j = A, \ldots, N 
\end{cases} \)

Then the horizontal components of the \( P_{ij} \) has been added and scores of the different criteria has been obtained. Based on these scores, the criteria has been prioritized.

Step 8. In this step, consistency ratio has been find out using following formula.

\[
\text{Consistency Ratio} = \frac{\xi}{\text{Consistency Index}}
\] (9)

To determine consistency index, the following equation has been used (Rezaei, 2015).
\[
\xi^2 - (1 + 2a_j)\xi + (a_j^2 - a_j) = 0,
\] (10)
where \( \xi \) varies from 1/9 to 9. Taking maximum of all the minimum values of \( \xi \), we will get consistency index.
2.2.1 Numerical example

In this section, we implemented the GBCM to solve two MCDM problems. first problem is transportation mode problem (for one expert) and second problem is car selection (for three expert).

**Example 1:** A company needs to select an optimal transportation mode too deliver the products to a market. We solved transportation mode problem using proposed method in this paper.

Step 1. Three criteria Load Flexibility, Accessibility and Cost are selected for this company.

Step 2. Cost is chosen as the base-criterion.

Step 3. Now, pairwise comparisons are done to determine the relative importance of base-criterion to the other criteria (Table 2).

<table>
<thead>
<tr>
<th>Base-criterion</th>
<th>Load flexibility</th>
<th>Accessibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>cost</td>
<td>[7, 8]</td>
<td>[1, 2]</td>
</tr>
</tbody>
</table>

Step 4. Grey linear model for this problem is formed as follows:

\[
\min \otimes \xi \\
\text{s.t.} \\
\otimes w_1 - [7,8] \otimes w_2 \leq \otimes \phi_2, \\
- \otimes w_1 + [7,8] \otimes w_2 \leq \otimes \phi_2, \\
\otimes \phi_2 \geq 0, \\
\otimes \phi_2 \geq \otimes \xi + 5.228 \ast 1 \ast \otimes w_2 - 5.228 \ast 1, \\
\otimes \phi_2 \leq 5.228 \ast 1 \ast \otimes w_2, \\
\otimes \phi_2 \leq \otimes \xi, \\
\otimes w_1 - [1,2] \otimes w_3 \leq \otimes \phi_3, \\
- \otimes w_1 + [1,2] \otimes w_3 \leq \xi \ast \otimes w_3, \\
\otimes \phi_3 \geq r_0, \\
\otimes \phi_3 \geq \otimes \xi + 5.228 \ast 1 \ast \otimes w_3 - 5.228 \ast 1, \\
\otimes \phi_3 \leq 5.228 \ast 1 \ast \otimes w_3, \\
\otimes \phi_3 \leq \xi, \\
\otimes w_1 + \otimes w_2 + \otimes w_3 = [0.8, 1.2] \\
\otimes w_1 \geq 0, \otimes w_2 \geq 0, \otimes w_3 \geq 0. \\
\tag{11}
\]

After solving this grey model using positioned programming technique, the weight values of the criteria are obtained. Table 3 demonstrate the weight values.

<table>
<thead>
<tr>
<th>weights</th>
<th>Lower</th>
<th>Upper</th>
</tr>
</thead>
<tbody>
<tr>
<td>\otimes w_1</td>
<td>0.4923076925</td>
<td>0.5600000006</td>
</tr>
<tr>
<td>\otimes w_2</td>
<td>0.0615384614</td>
<td>0.0800000000</td>
</tr>
<tr>
<td>\otimes w_3</td>
<td>0.2461538459</td>
<td>0.5599999991</td>
</tr>
<tr>
<td>\otimes \xi</td>
<td>0.0</td>
<td>0.0</td>
</tr>
</tbody>
</table>

Step 5. Further Table 4 represents the calculated normalized weights.
Step 6. This step involves formation of grey possibility degree and prioritization of the criteria. Grey possibility degree is formed as:

\[
GP_{ij} = \begin{bmatrix}
0.5 & 1 & 0.82 \\
0 & 0.5 & 0 \\
0.17 & 1 & 0.5
\end{bmatrix}
\]  \hspace{1cm} (12)

\[
P_{ij} = \begin{bmatrix}
0 & 1 & 1 & 2 \\
0 & 0 & 0 & 0 \\
0 & 1 & 0 & 1
\end{bmatrix}
\]  \hspace{1cm} (13)

Based on the sum values of horizontal component in \( P_{ij} \), criteria are prioritized as in following order Cost > Accessibility > Load Flexibility.

**Result for Transportation Mode Problem** indicates that the cost criteria have major effect than accessibility and accessibility have greater effect than load flexibility. From the Table 4 we can see that value of \( \xi \) become zero which leads to the zero-consistency ratio.

**Example 2**: Here we are solving an another MCDM problem about selection of car based on some important criteria. Three experts are taken for multi criteria group decision making. We can determine many criteria for car selection. In the current example, five criteria are under consideration as price, quality, comfort, safety and style.

Step 1. Set of criteria determined by experts is (price, quality, comfort, safety, style).

Step 2. Each expert chooses any one criteria among the different criteria as base criterion. Here all three experts selected price as base criterion.

Step 3. Now, using grey linguistic variables pairwise comparison (Table 5) of base-criterion to other criteria is done.

<table>
<thead>
<tr>
<th>Experts</th>
<th>Base-Criterion</th>
<th>Quality</th>
<th>Comfort</th>
<th>Safety</th>
<th>Style</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Price</td>
<td>[2, 3]</td>
<td>[6, 7]</td>
<td>[6, 7]</td>
<td>[8, 9]</td>
</tr>
<tr>
<td>2</td>
<td>Price</td>
<td>[4, 5]</td>
<td>[7, 8]</td>
<td>[8, 9]</td>
<td>[6, 7]</td>
</tr>
<tr>
<td>3</td>
<td>Price</td>
<td>[1/3,1/2]</td>
<td>[8, 9]</td>
<td>[6, 7]</td>
<td>[7, 8]</td>
</tr>
</tbody>
</table>

Step 4. Grey model for the first decision maker is formed as:

\[
\min \otimes \xi
\]

s.t.

\[
\otimes w_1 \otimes [2,3], \otimes w_2 \leq \otimes \emptyset_2,
\]

\[
- \otimes w_1 + [2,3] \otimes w_2 \leq \otimes \emptyset_2,
\]

\[
\otimes \emptyset_2 \geq 0,
\]

\[
\otimes \emptyset_2 \geq \otimes \xi + Cl.A \otimes w_2 - Cl.A,
\]

\[
\otimes \emptyset_2 \leq Cl.A \otimes w_2,
\]

\[
\otimes \emptyset_2 \leq \xi,
\]

\[
\otimes w_1 \otimes [6,7], \otimes w_3 \leq \otimes \emptyset_3,
\]

\[
- \otimes w_1 + [6,7] \otimes w_3 \leq \otimes \emptyset_3,
\]

\[
\otimes \emptyset_3 \geq 0,
\]

\[
\otimes \emptyset_3 \geq \otimes \xi + Cl.A \otimes w_3 - Cl.A,
\]
\( \otimes \theta_3 \leq Cl.A \otimes w_3 \),
\( \otimes \theta_3 \leq \xi \),
\( \otimes w_1 - [6.7] \otimes w_4 \leq \otimes \emptyset_4 \),
\( - \otimes w_1 + [6.7] \otimes w_4 \leq \otimes \emptyset_4 \),
\( \otimes \emptyset_4 \geq 0 \),
\( \otimes \emptyset_4 \geq \xi + Cl.A \otimes w_4 - Cl.A \),
\( \otimes \emptyset_4 \leq Cl.A \otimes w_4 \),
\( \otimes \emptyset_4 \leq \xi \),
\( \otimes w_1 - [8.9] \otimes w_5 \leq \otimes \emptyset_5 \),
\( - \otimes w_1 + [8.9] \otimes w_5 \leq \otimes \emptyset_5 \),
\( \otimes \emptyset_5 \geq 0 \),
\( \otimes \emptyset_5 \geq \xi + Cl.A \otimes w_5 - Cl.A \),
\( \otimes \emptyset_5 \leq Cl.A \otimes w_5 \),
\( \otimes \emptyset_5 \leq \xi \),
\( \otimes w_1 + \otimes w_2 + \otimes w_3 + \otimes w_4 + \otimes w_5 = [0.8,1.2] \)
\( \otimes w_1 \geq 0, \otimes w_2 \geq 0, \otimes w_3 \geq 0, \otimes w_4 \geq 0, \otimes w_5 \geq 0 \) \hspace{1cm} (14)

After solving this grey model using positioned programming method, the weights values of the criteria for the first decision maker are obtained (Table 6). Similarly, weight values can be obtained for the second and third decision maker (Table 7 and Table 8) as well.

<td>[0.236,0.268]</td>
</tr>
<tr>
<td>quality</td>
<td>0.473517322</td>
<td>0.814446733</td>
<td>[0.473,0.814]</td>
</tr>
<tr>
<td>comfort</td>
<td>0.026306518</td>
<td>0.033595928</td>
<td>[0.026,0.033]</td>
</tr>
<tr>
<td>safety</td>
<td>0.033822666</td>
<td>0.044794570</td>
<td>[0.033,0.044]</td>
</tr>
<tr>
<td>style</td>
<td>0.029954833</td>
<td>0.038395346</td>
<td>[0.029,0.038]</td>
</tr>
<tr>
<td>( \otimes \xi )</td>
<td>0.0</td>
<td>0.0</td>
<td>[0,0]</td>
</tr>
</tbody>
</table>
Step 5. Using grey geometric mean, aggregated weight are obtained as follows (Table 9).

<table>
<thead>
<tr>
<th>Weight</th>
<th>Lower</th>
<th>Upper</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\otimes w_1$</td>
<td>0.381366172</td>
<td>0.48954406</td>
</tr>
<tr>
<td>$\otimes w_2$</td>
<td>0.194829663</td>
<td>0.35420700</td>
</tr>
<tr>
<td>$\otimes w_3$</td>
<td>0.047921675</td>
<td>0.07041719</td>
</tr>
<tr>
<td>$\otimes w_4$</td>
<td>0.050102874</td>
<td>0.07413005</td>
</tr>
<tr>
<td>$\otimes w_5$</td>
<td>0.047921675</td>
<td>0.07041719</td>
</tr>
</tbody>
</table>

Step 6. The normalized weights are obtained as follows (Table 10).

<table>
<thead>
<tr>
<th>Weight</th>
<th>Lower</th>
<th>Upper</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\otimes w_1^*$</td>
<td>0.428294979</td>
<td>0.549784635</td>
</tr>
<tr>
<td>$\otimes w_2^*$</td>
<td>0.218804321</td>
<td>0.397793750</td>
</tr>
<tr>
<td>$\otimes w_3^*$</td>
<td>0.053818650</td>
<td>0.079082339</td>
</tr>
<tr>
<td>$\otimes w_4^*$</td>
<td>0.056268256</td>
<td>0.083252082</td>
</tr>
<tr>
<td>$\otimes w_5^*$</td>
<td>0.053818650</td>
<td>0.079082339</td>
</tr>
</tbody>
</table>

Step 7. In this step, the criteria are prioritized using grey possibility degree.

\[
GP_{ij} = \begin{bmatrix}
0.5 & 1 & 1 & 1 & 1 \\
0 & 0.5 & 1 & 1 & 1 \\
0 & 0 & 0.5 & 0.47 & 0.5 \\
0 & 0 & 0.59 & 0.5 & 0.59 \\
0 & 0 & 0.5 & 0 & 0.5
\end{bmatrix}
\]  
\[
P_{ij} = \begin{bmatrix}
0 & 1 & 1 & 1 & 1 & 1 \\
0 & 0 & 1 & 1 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 1 & 2 \\
0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}
\]

Based on the sum values of the horizontal component of the $P_{ij}$, criteria can prioritize as Price > Quality > Safety > Comfort > Style.

Above results show that for selection of a car price is considered as most preferable criteria. Quality of a car is second most important criteria. Further, safety is concluded as third important criteria whereas comfort and style have the same weights.

2.3 Comparative Analysis

In this section, results of numerical example by the proposed method GBCM compared with the GBWM (Mahmoudi et al. 2020). Results of GBCM are obtained by using on position programming method based on ideal and critic model. Table 11, Table 12, and Table 13 display the comparisons between proposed method and the GBWM (Mahmoudi et al. 2020).

<td>4</td>
</tr>
</tbody>
</table>

Results of comparison are as follows:

- Ranking of criteria using GBCM (proposed method) is same as by using GBWM (Mahmoudi et al. 2020) with different input values.
- The results obtained by using GBCM (proposed method) is more reliable than the one calculated by GBWM. Smaller consistency ratio is the main reason behind this reliability.
- In the proposed method, we do less pairwise comparison as compared to GBWM method which consists best to others as well as others to worst pairwise comparison.

### 3. A case study

OTT (Over the Top) are the media platforms that make possible to deliver video, TV shows and live feeds on the internet. In India, there are various OTT platforms including Amazon Prime, Hotstar Disney, Netflix, Voot, ZEE5, Sony LIV and many others. Now a days this type of technology is largely affecting the media and entertainment industry. One can prefer any OTT service based on its content, accessibility and different other factors. In the current study, we investigate the fastest growing OTT platform in India based on some important criteria. The weights of the criteria are determined by the proposed method and ranking of the OTT platform is done by using TOPSIS method.
3.1 Listing the alternatives and criteria

There are many factors which comes in mind of users for choosing any OTT platform. We have taken 4 criteria that majorly effects the popularity of any OTT platform. The considered criteria are described as follows:

1. Cost-efficient ($C_1$): It describes about monthly or yearly price of any OTT platform. Usually, user or decision maker chooses that platform which have less monthly or annually price with good content quality. Range of cost-efficient differs according to the platform and the content provided by it.

2. Content Language ($C_2$): An OTT service contains many contents as movies, reality shows, TV serial, web series, news, sports and many others. There are many languages in which these contents are available. So, the availability of more content languages may increase the use of any OTT platform.

3. Monthly Active Users ($C_3$): This factor indicates the monthly subscribers of any OTT platform. In our daily life we use any product or electronic equipment and many other things by reading reviews of other users after using them. Obviously, that product is preferred which have more and positive reviews. Likewise, there is a great role of users or followers of any OTT platform behind its popularity.

4. Rating ($C_4$): This includes giving rating stars to any platform out of 5-star scale. That platform which has greater number of stars taken as most popular platform.

In this study, cost-efficient ($C_1$) is taken as non-beneficial attribute while all remaining attributes content language ($C_2$), monthly active users ($C_3$), rating ($C_4$) are taken as beneficial attributes. The following 5 well known Over the Top platforms have taken as alternative to analyse their performance based on above mentioned attributes or criteria.

1. Disney Hotstar ($A_1$)
2. ZEE5 ($A_2$)
3. Netflix ($A_3$)
4. Amazon Prime Video ($A_4$)
5. Sony LIV ($A_5$)

3.2 Determination of the weights of criteria by Grey Base-Criterion Method

The data of OTT platforms in India is collected from https://dailyweblife.com/best-ott-apps-india-2020/. The decision matrix $d_{ij}$ is given in the Table 14.

<table>
<thead>
<tr>
<th>Alternatives</th>
<th>$C_1$</th>
<th>$C_2$</th>
<th>$C_3$</th>
<th>$C_4$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disney Hotstar</td>
<td>1499</td>
<td>8</td>
<td>3000000000</td>
<td>4</td>
</tr>
<tr>
<td>ZEE5</td>
<td>999</td>
<td>12</td>
<td>76400000</td>
<td>3</td>
</tr>
<tr>
<td>Netflix</td>
<td>999</td>
<td>10</td>
<td>13400000</td>
<td>4.3</td>
</tr>
<tr>
<td>Amazon Prime Video</td>
<td>799</td>
<td>10</td>
<td>15800000</td>
<td>4</td>
</tr>
<tr>
<td>Sony LIV</td>
<td>499</td>
<td>4</td>
<td>65000000</td>
<td>3</td>
</tr>
</tbody>
</table>

The cost-efficient ($C_1$) has choosen as base criterion. Further, the pairwise comparison matrix is done as shown in Table 15.

<table>
<thead>
<tr>
<th>Base-criterion</th>
<th>Content Language</th>
<th>Monthly Active Users</th>
<th>Rating</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cost-efficient</td>
<td>[1,2]</td>
<td>[2,3]</td>
<td>[1/9,1/8]</td>
</tr>
</tbody>
</table>
Grey linear model for this pairwise comparison is given as follows:

\[
\begin{align*}
& \text{Min } \otimes \xi \\
\text{s.t.} & \quad |\otimes w_1 - [1,2] \otimes w_2| \leq \xi \otimes w_2, \\
& \quad \otimes w_2 \otimes \xi \geq 0, \\
& \quad \otimes w_2 \otimes \xi \geq \xi + 5.228 \times 1 \times \otimes w_2 - 5.228 \times 1, \\
& \quad \otimes w_2 \otimes \xi \leq 5.228 \times 1 \times \otimes w_2, \\
& \quad \otimes w_2 \leq \otimes \xi, \\
& \quad |\otimes w_1 - [2,3] \otimes w_3| \leq \xi \otimes w_3, \\
& \quad \otimes w_3 \otimes \xi \geq 0, \\
& \quad \otimes w_3 \otimes \xi \geq \xi + 5.228 \times 1 \times \otimes w_3 - 5.228 \times 1, \\
& \quad \otimes w_3 \otimes \xi \leq 5.228 \times 1 \times \otimes w_3, \\
& \quad \otimes w_3 \leq \otimes \xi, \\
& \quad |\otimes w_1 - [1/9,1/8] \otimes w_4| \leq \xi \otimes w_4, \\
& \quad \otimes w_4 \leq \otimes \xi, \\
& \quad \otimes w_4 \otimes \xi \geq \xi + 5.228 \times 1 \times \otimes w_4 - 5.228 \times 1, \\
& \quad \otimes w_4 \otimes \xi \leq 5.228 \times 1 \times \otimes w_4, \\
& \quad \otimes w_4 \leq \otimes \xi, \\
& \quad \otimes w_1 + \otimes w_2 + \otimes w_3 + \otimes w_4 = [0.8,1.2] \\
& \quad \otimes w_1, \otimes w_2, \otimes w_3 \geq 0 \\
\end{align*}
\]

After solving this model, the obtained grey weights of the attributes are given in Table 16 and Table 17 shows the calculated normalized weights.

### Table 16. Weights of the attributes.

</tr>
</tbody>
</table>

After that, ideal best and ideal worst is determined for each criteria (Table 20) and then values of $s_i^-$ and $s_i^+$ are calculated (Table 21). Finally, preference score is calculated by using following formula:

$$P_i = \frac{s_i^-}{s_i^+ + s_i^-}$$

Table 20. Ideal best and ideal worst solution for the criteria

</tr>
</tbody>
</table>

Based on the preference score value, alternatives are ranked as follows: Amazon Prime Video > Disney Hotstar > Netflix > ZEE5 > Sony LIV. Amazon Prime Video is found as the fastest growing OTT platform in India.

4. Conclusion

The goal of this study is to introduce the notion of GBCM which provides the decision maker a significant way to deal with incomplete and poor data with zero stability ratio, less calculation and thus can be employed on a wide range of applications. BCM is an important method for MCDM as it consists zero consistency ratio and less
computations. Also, it is difficult for decision maker to exactly define the belongings and non-belongings through crisp numbers. In this situation grey numbers is a good choice as they provide range or interval to define belongings and non-belongings. By this property, grey information has been introduced in BCM decision-making method. Further, we have established the extended GBCM method. After that numerical examples are illustrated. In addition, comparison analysis has been conducted between the proposed method and GBWM method (Mahmoudi et al. 2020) which demonstrates the advantage of the proposed method. At last, in order to validate the applicability of GBCM, a case study of selecting the fastest growing OTT platform in India is presented. This approach became successful as Amazon Prime Video is found as the fastest growing OTT platform in India.

There are many good research ideas for scholars to introduce different methods for solving grey linear programming in BCM. Some other methods for linearization may be use for getting more accurate solution for decision-making problem.
